Ionized calcium (Ca^{2+}) is a universal signaling element that transmits an extracellular stimulus from the surface of cells to intracellular structures and molecules. Ca^{2+} regulates many cellular processes, including gene transcription, proliferation, differentiation, secretion and apoptosis. The key to this pleiotropic activity is the complex spatiotemporal organization of the rise of intracellular Ca^{2+} (Ca^{2+} signal), which, acting on certain effectors, initiates specific signaling events in the cell. Violation of the mechanisms responsible for the regulation of cellular Ca^{2+} or exceeding stimulation of receptors leads to cell death. The review article addresses the main mechanisms underlying the cellular organization of Ca^{2+} signals. A brief retrospective of the development of modern concept of Ca^{2+} signaling and its role in the vital functions of the organism is presented. Special attention is given to the basic intracellular systems that provide the organization, spatio-temporal regulation and encoding of Ca^{2+} signals.

Keywords: Ca^{2+} signaling, Ca^{2+} microdomains, InsP3R, RyR, and NAADP receptors, Ca^{2+} channels of VOCs, TRP, CRAC
